Surface conformation effects in the main-chain dynamics of densely functionalized polypeptides. Some extensions of the peptide model originally proposed by de Gennes and Brochard are used to describe the short-time dynamics of dense polypeptides. The motion of the backbones is treated using a rigid-body simulation model for uncoiling random chain conformations in which each monomer is allowed to rotate independently about its center of mass and translate freely. The rotational freedom of each monomer depends on its orientation with respect to the other monomers in the chain. The chains are assumed to be modeled by a collection of rigid segments representing functional groups. The monomer-segment dimension is treated as a free parameter to optimize the agreement between the experimentally measured results and the predictions of the model.

Q: Javascript in nodejs I am new to nodejs and trying to understand the code below. I know what the functions do, but not what the `_read` function does? The `read` function gets a string and prints it to the console. What does it do? `var ncdump = require('ncdump');` `var dumpData = 'testdata';` `var _read = function(_type, _dump) { console.log('Start _read, dump:'+ _dump); ncdump.dump(_dump, 'nc-dump', function(error) { console.log(error); }); console.log('End _read'); } _read('file', 'test');` `_read('socket', 'test');` `_read('tcp', 'test');`

A: `_read` is an internal function that does some housekeeping stuff in NodeJS. The purpose of the function is to call `console.log(error)` at the end of `ncdump.dump()`. The function is getting a number or name of the type of the dump (e.g. `socket`), and a string that is "test" as the dump. Hope this helps!

What's New In Adobe Photoshop CS3?

1. Field of the Invention The present invention relates to a photomask and its manufacturing method, and in particular to a photomask for use as a semiconductor micro-machining mask such as an ArF exposure mask or an ArF immersion-etching resist, a method of manufacturing such a photomask, and a micro-machining mask prepared using such a photomask.

2. Description of the Related Art As semiconductor integration circuits are progressively miniaturized, a process window, which is a margin between the upper and lower limits of the resolution in a photolithographic process, is also being narrowed. In particular, for a deep-ultraviolet photolithographic process using an ArF excimer laser as a light source, a process window of about 0.2 μm is required. However, it is difficult to match the window by merely increasing the ArF excimer laser wavelength. One of the measures taken for solving this problem is to reduce the wavelength of a light source for illumination, such as an electron beam (EB). On the other hand, in the above-mentioned semiconductor micro-machining, to achieve a higher pattern resolution, a micro-pattern should be formed at a depth from a substrate surface of 0.1 μm or less. Further, since pattern forming and etching requires a high etching selectivity between materials, an etching depth of about 0.1 μm should be set as the upper limit. To form an optical mask used for a photolithographic process, wherein a pattern is transferred from a photomask to a wafer, a light-shielding pattern is also required. For the light-shielding pattern, a material selected from a group consisting of chromium (Cr), chromium-silicon (Cr—Si), silicon nitride (Si_3N_4), and tungsten (W) is normally used. To form a light-shielding pattern without dislocations and other defects, a design rule such as a line-and-space pattern is preferred. If a light-shielding pattern for a photomask to be used for photolithography is formed as a line-and-space pattern, it is generally said that the line-and-space pattern is formed in a self-aligned manner, wherein the light-shielding film is formed on a resist and is etched, while the resist remains on the resist non-depressed by the upper portions of
